joint work with P. Fougères and B. Zegarlinski

Introduction

Our result

The proof

The general case

Reversible chemical reaction (diffusion)

$$\sum_{i=1}^q \alpha_i \mathcal{A}_i \rightleftharpoons \sum_{i=1}^q \beta_i \mathcal{A}_i,$$

$\mathcal{A}_i$ are species with $\alpha_i \neq \beta_i$.

- The law of action mass (Waage and Guldberg in 1864) says u_i are concentration

$$\frac{d}{dt} u_i = (\beta_i - \alpha_i) \left(k \prod_{j=1}^q u_j^{\alpha_j} - \ell \prod_{j=1}^q u_j^{\beta_j} \right),$$

- With a diffusion term

$$\partial_t u_i = L_i u_i + (\beta_i - \alpha_i) \left(k \prod_{j=1}^q u_j^{\alpha_j} - \ell \prod_{j=1}^q u_j^{\beta_j} \right),$$

L_i is an (diffusion) operator.

General problem : Chemical reversible reaction associated to an incompressible fluid

- Incompressible Navier-Stokes equation for the fluid v :

$$\partial_t v = \alpha L v + (v \cdot \nabla)(v) + f(T, t, x)$$

with $\nabla^* v = 0$ (or $\nabla v = 0$)

- The temperature T :

$$\partial_t T = \beta L T + (v \cdot \nabla)(T) + H(\vec{u})\Phi(T)$$

The function H describe how the temperature depends on the chemical reaction and $\Phi(T) = \exp(-\gamma/T)$

- The concentration of the species

$$\partial_t u_i = C_i L u_i + (v \cdot \nabla)(u_i) + (\beta_i - \alpha_i) \left(k \prod_{j=1}^q u_j^{\alpha_j} - \ell \prod_{j=1}^q u_j^{\beta_j} \right) \Phi(T).$$

Our main example (for understanding computations) :

The *two-by-two* case with $L_i = C_i L$

$$\mathcal{A}_1 + \mathcal{A}_2 \rightleftharpoons \mathcal{B}_1 + \mathcal{B}_2,$$

and the equation can be formulated as follow

$$\begin{cases} \partial_t u_1 = C_1 L u_1 - \lambda (u_1 u_2 - v_1 v_2) \\ \partial_t u_2 = C_2 L u_2 - \lambda (u_1 u_2 - v_1 v_2) \\ \partial_t v_1 = C_3 L v_1 + \lambda (u_1 u_2 - v_1 v_2) \\ \partial_t v_2 = C_4 L v_2 + \lambda (u_1 u_2 - v_1 v_2) \end{cases}$$

with $u_i(t, x)$, $t \geq 0$, $x \in \mathbb{M}$.

Main assumptions :

- L is a Markov semigroup associated to $(P_t)_{t \geq 0}$ on $\mathbb{M}$: $P_t f$ is solution of the *parabolic* equation

$$\partial_t u = Lu,$$

with $u(t = 0) = f$.

- L is reversible with respect to the *probability measure* μ ,

$$\forall f, g, \quad \int f L g d\mu = \int g L f d\mu.$$

- L satisfies a logarithmic Sobolev inequality

$$\text{Ent}_\mu(u^2) \equiv \mu(u^2 \log \frac{u^2}{\mu(u^2)}) \leq C_{LS} \mathcal{E}(u),$$

with

$$\mathcal{E}(u, v) = -\mu(v Lu).$$

Examples :

- ▶ In $\mathbb{R}^n$, the Ornstein-Uhlenbeck semigroup

$$L = \Delta - x \cdot \nabla$$

with the reversible measure $\mu(dx) = \frac{e^{-||x||^2/2}}{(2\pi)^{n/2}} dx$ then $C_{LS} = 2$.

More generally

$$L = \Delta - \nabla \Psi \cdot \nabla$$

such that $\text{Hess}(\psi) \geq \lambda \text{Id}$ with $\lambda > 0$, then $C_{LS} = 2/\lambda$.

- ▶ In a Riemannian setting (uniform bound on the Ricci curvature).
- ▶ In a discrete setting (Markov chain).
- ▶ In an infinite dimension setting (Gibbs measures).

Two questions :

- ▶ **Existence theorem** : find conditions on $\mathbb{M}$, L , C_i and L such that there exists a *positive* solution (weak, strong, mild...) on $\mathbb{R}_+$.
 - ▶ On $\Omega \subset \mathbb{R}^n$, bounded, with bounded initial conditions and boundary conditions.

$$\begin{cases} \partial_t u_1 = C_1 L u_1 - \lambda (u_1 u_2 - v_1 v_2) \\ \partial_t u_2 = C_2 L u_2 - \lambda (u_1 u_2 - v_1 v_2) \\ \partial_t v_1 = C_3 L v_1 + \lambda (u_1 u_2 - v_1 v_2) \\ \partial_t v_2 = C_4 L v_2 + \lambda (u_1 u_2 - v_1 v_2) \end{cases}$$

the C_i 's could be different. (M. Pierre, L. Desvillettes, Rothe and coauthors...).

- ▶ On $\mathbb{R}^n$ with restriction of the number of species (S. Zelik and coauthors).
- ▶ **Asymptotic behaviour** : there exists a unique steady state of the solution (up to conservation mass).

The abstract equation

$$\begin{cases} \frac{\partial}{\partial t} \vec{u}(t) &= \mathfrak{C} L \vec{u}(t) + G(\vec{u}(t)) \vec{\lambda}, & t > 0 \\ \vec{u}(0) &= \vec{f} \end{cases} \quad (\text{RDE})$$

where

- ▶ $\vec{u}(t, x)$ is a function from $[0, \infty) \times \mathbb{M}$ to $\mathbb{R}^4$
- ▶ $\vec{\lambda} = \lambda(-1, -1, 1, 1) \in \mathbb{R}^4$, $\lambda > 0$;
- ▶ $G(\vec{u}) = u_1 u_2 - u_3 u_4$.
- ▶

$$\mathfrak{C} = \begin{pmatrix} C_1 & 0 & 0 & 0 \\ 0 & C_2 & 0 & 0 \\ 0 & 0 & C_3 & 0 \\ 0 & 0 & 0 & C_4 \end{pmatrix},$$

we assume that $C_1 = C_3$ and $C_2 = C_4$.

- ▶ the initial datum is $\vec{f} = (f_1, f_2, f_3, f_4)$.

Weak solutions :

Let $T > 0$, $\vec{u} \in \mathbb{L}^2([0, T], \mathcal{D}^4)$ is a weak solution of (RDE) on $[0, T]$ provided, for any $\vec{\varphi} \in C^\infty([0, T], (\mathcal{D} \cap \mathbb{L}^\Phi(\mu))^4)$,

$$\begin{aligned} & - \int_0^t \sum_{i=1}^4 \mu(u_i(s) \partial_s \varphi_i(s)) ds + \left[\sum_{i=1}^4 \mu(u_i(t) \varphi_i(t) - u_i(0) \varphi_i(0)) \right] \\ & = - \int_0^t \sum_{i=1}^4 C_i \mathcal{E}(u_i(s), \varphi_i(s)) ds + \int_0^t \sum_{i=1}^4 \lambda_i \mu(\varphi_i(s) G(\vec{u}(s))) ds. \end{aligned}$$

where $\mathbb{L}^\Phi(\mu) = \{u, \exists \gamma > 0, \text{ s.t. } \mu(e^{\gamma|u|}) < \infty\}$

Theorem

Let (L, μ) be a Markov generator satisfying a log-Sobolev inequality with constant C_{LS} such that

$$\max(4, 3/C_1, 3/C_2) \lambda_{C_{LS}} < \gamma.$$

Then $\forall \vec{f}$ s.t.

$$\mu(e^{\gamma f_i}) < \infty, i = 1, \dots, 4,$$

there exists a unique weak solution $\vec{u}$ of (RDE) $[0, \infty)$.

$$\frac{\partial}{\partial t} \vec{u}(t) = \mathfrak{C} L \vec{u}(t) + G(\vec{u}(t)) \vec{\lambda}, \quad t > 0$$

Moreover, $\vec{u} \geq 0$ and satisfies on $\mathbb{R}_+$,

$$\mu(e^{\gamma u_i(t)}) \leq \mu(e^{\gamma f_i}).$$

An iterative procedure :

Let define $(\vec{u}^{(n)})_{n \in \mathbb{N}}$

- ▶ for all $n \in \mathbb{N}$, $\vec{u}^{(n)}(t=0) = \vec{f}$;
- ▶ for $n=0$, $\partial_t \vec{u}^{(0)}(t) = \mathfrak{C}L\vec{u}^{(0)}(t)$
- ▶ for any $n \geq 1$,

$$\partial_t \vec{u}^{(n)} = \mathfrak{C}L\vec{u}^{(n)} + \vec{\lambda}(u_1^{(n)}v_2^{(n-1)} - u_3^{(n)}v_4^{(n-1)}).$$

The sequence is well defined : for $n=0$, the solution is given by $(P_t)_{t \geq 0}$.

Then since $C_1 = C_3$,

$$\begin{cases} \partial_t(u_1^{(n)} + u_3^{(n)}) = C_1 L(u_1^{(n)} + u_3^{(n)}) \\ \partial_t(u_2^{(n)} + u_4^{(n)}) = C_2 L(u_2^{(n)} + u_4^{(n)}) \end{cases}$$

then

$$\partial_t u_1^{(n)} = C_1 L u_1^{(n)} - \lambda u_1^{(n)}(u_2^{(n-1)} + u_3^{(n-1)}) + \lambda P_{C_1 t}(f_1 + f_3)u_4^{(n-1)}.$$

with initial datum f_1

Existence and positivity of the sequence follows from this Lemma, with $A(t) = \lambda(u_2^{(n-1)} + u_3^{(n-1)})$ and $B(t) = \lambda P_{C_1 t}(f_1 + f_3)u_4^{(n-1)}$.

Lemma

Let $A = A(t, x) \geq 0 \in \mathbb{L}^\infty([0, T], \mathbb{L}^\Phi(\mu))$ and $B = B(t, x) \geq 0 \in \mathbb{L}^\infty([0, T], \mathbb{L}^2(\mu))$ for any $T > 0$ then the Cauchy problem

$$\begin{cases} \partial_t u(t) = Lu(t) - A(t) u(t) + B(t), \\ u(0) = f, f \in \mathbb{L}^2(\mu) \end{cases}$$

has a unique nonnegative solution $u \in \mathbb{L}^\infty([0, T], \mathbb{L}^2(\mu) \cap \mathcal{D})$.

A priori estimates :

Proposition

Let $\vec{u}^{(n)}$ (for any n) be a solution the sequence then

$$\int e^{\gamma(u_1^{(n)} + u_3^{(n)})} d\mu \leq \int e^{\gamma(f_1 + f_3)} d\mu$$

and similarly for $u_2^{(n)} + u_4^{(n)}$.

Proof : Formally since $\partial_t(u_1^{(n)} + u_3^{(n)}) = C_1 L(u_1^{(n)} + u_3^{(n)})$ then

$$\frac{d}{dt} \int e^{\gamma(u_1^{(n)} + u_3^{(n)})} d\mu = \int \gamma C_1 L(u_1^{(n)} + u_3^{(n)}) e^{\gamma(u_1^{(n)} + u_3^{(n)})} d\mu \leq 0,$$

which implies the result.

Convergence of the approximation procedure :

- **Idea** : for $\kappa > 0$, let considere

$$\Sigma_n(t) = \mu(|\vec{u}^{(n)} - \vec{u}^{(n-1)}|^2)(t) + \kappa \int_0^t \mathcal{E}(\vec{u}^{(n)} - \vec{u}^{(n-1)})(s) ds,$$

then $\sup_{t \in [0, T]} \Sigma_n(t)$ goes to 0 exponentially fast as $n \rightarrow \infty$ if $T > 0$ small enough ; Where

$$|\vec{u}|^2 = \sum_{i=1}^4 u_i^2 \quad \text{and} \quad \mathcal{E}(\vec{u}) = \sum_{i=1}^4 \mathcal{E}(u_i).$$

- **Main tool** : Relative entropy inequality, for any $f, g \geq 0$, $\gamma > 0$,

$$\mu(fg) \leq \frac{1}{\gamma} \mu \left(f \log \frac{f}{\mu(f)} \right) + \frac{\mu(f)}{\gamma} \log \mu(e^{\gamma g})$$

Estimate of the $\mathbb{L}^2$ -norm derivative :

We will focus on the $\mathbb{L}^2$ -norm of $u_1^{(n)}$:

$$\begin{aligned} \frac{1}{2} \frac{d}{dt} \mu((u_1^{(n)} - u_1^{(n-1)})^2) &= C_1 \mu((u_1^{(n)} - u_1^{(n-1)}) L(u_1^{(n)} - u_1^{(n-1)})) \\ &\quad - \lambda \mu((u_1^{(n)} - u_1^{(n-1)})(u_1^{(n)} u_2^{(n-1)} - u_3^{(n)} u_4^{(n-1)} - u_1^{(n-1)} u_2^{(n-2)} + u_3^{(n-1)} u_4^{(n-2)})), \end{aligned}$$

or after natural bilinear handlings,

$$\begin{aligned} \frac{1}{2} \frac{d}{dt} \mu((u_1^{(n)} - u_1^{(n-1)})^2) &= -C_1 \mathcal{E}(u_1^{(n)} - u_1^{(n-1)}) - \lambda \mu((u_1^{(n)} - u_1^{(n-1)})^2 u_2^{(n-1)}) \\ &\quad - \lambda \mu((u_1^{(n)} - u_1^{(n-1)})(u_2^{(n-1)} - u_2^{(n-2)}) u_1^{(n-1)}) \\ &\quad + \lambda \mu((u_1^{(n)} - u_1^{(n-1)})(u_3^{(n)} - u_3^{(n-1)}) u_4^{(n-1)}) \\ &\quad + \lambda \mu((u_1^{(n)} - u_1^{(n-1)})(u_4^{(n-1)} - u_4^{(n-2)}) u_3^{(n-1)}). \end{aligned}$$

Since $\vec{u}^{(n-1)}$ is nonnegative, and by the quadratic inequality $ab \leq a^2/2 + b^2/2$, one gets

$$\begin{aligned} \frac{1}{2} \frac{d}{dt} \mu((u_1^{(n)} - u_1^{(n-1)})^2) &\leq -C_1 \mathcal{E}(u_1^{(n)} - u_1^{(n-1)}) \\ &+ \frac{\lambda}{2} \mu((u_1^{(n)} - u_1^{(n-1)})^2 u_1^{(n-1)}) + \frac{\lambda}{2} \mu((u_2^{(n-1)} - u_2^{(n-2)})^2 u_1^{(n-1)}) \\ &+ \frac{\lambda}{2} \mu((u_1^{(n)} - u_1^{(n-1)})^2 u_4^{(n-1)}) + \frac{\lambda}{2} \mu((u_3^{(n)} - u_3^{(n-1)})^2 u_4^{(n-1)}) \\ &+ \frac{\lambda}{2} \mu((u_1^{(n)} - u_1^{(n-1)})^2 u_3^{(n-1)}) + \frac{\lambda}{2} \mu((u_4^{(n-1)} - u_4^{(n-2)})^2 u_3^{(n-1)}). \end{aligned}$$

All the similar terms are then estimated thanks to the relative entropy inequality. For instance,

$$\begin{aligned} \mu((u_1^{(n)} - u_1^{(n-1)})^2 u_1^{(n-1)}) &\leq \frac{1}{\gamma} \text{Ent}_\mu((u_1^{(n)} - u_1^{(n-1)})^2) \\ &\quad + \frac{1}{\gamma} \mu((u_1^{(n)} - u_1^{(n-1)})^2) \log \mu(e^{\gamma u_1^{(n-1)}}). \end{aligned}$$

The logarithmic Sobolev inequality and the a priori bound described in the Proposition give

$$\mu((u_1^{(n)} - u_1^{(n-1)})^2 u_1^{(n-1)}) \leq \frac{C_{LS}}{\gamma} \mathcal{E}(u_1^{(n)} - u_1^{(n-1)}) + \frac{D}{\gamma} \mu((u_1^{(n)} - u_1^{(n-1)})^2),$$

where

$$D = \max \left\{ \log \mu(e^{\gamma(f_1 + f_3)}), \log \mu(e^{\gamma(f_2 + f_4)}) \right\}.$$

Recall

$$\Sigma_n(t) = \mu(|\vec{u}^{(n)} - \vec{u}^{(n-1)}|^2)(t) + \kappa \int_0^t \mathcal{E}(\vec{u}^{(n)} - \vec{u}^{(n-1)})(s) ds,$$

then

$$\begin{aligned} \Sigma_n(t) &\leq D \frac{4\lambda}{\gamma} \int_0^t \Sigma_n(s) ds \\ &\quad + D \frac{4\lambda}{\gamma} \left(\int_0^t \mu(|\vec{u}^{(n-1)} - \vec{u}^{(n-2)}|^2)(s) ds \right. \\ &\quad \left. + \frac{C_{LS}}{D} \int_0^t \mathcal{E}(\vec{u}^{(n-1)} - \vec{u}^{(n-2)})(s) ds \right). \end{aligned}$$

Gronwall argument implies local existence :

$$\sup_{t \in [0, T]} \Sigma_n(t) \leq \eta(T) \sup_{t \in [0, T]} \Sigma_{n-1}(t),$$

where $\eta(T) = \frac{4\lambda}{\gamma} e^{D \frac{2\lambda}{\gamma} T} (DT + C_{LS}) < 1$ if $T > 0$ small enough.

Existence of the weak solution on $[0, T]$:

Let $T > 0$ fixed as before, if $\varphi \in \mathcal{C}^\infty([0, T], (\mathcal{D} \cap \mathbb{L}^\Phi(\mu))^4)$,

$$\begin{aligned} \int_0^t \mu(\varphi \partial_s u_1^{(n)})(s) ds &= C_1 \int_0^t \mu(\varphi L u_1^{(n)})(s) ds \\ &\quad - \lambda \int_0^t \mu(\varphi u_1^{(n)} u_2^{(n-2)})(s) ds + \lambda \int_0^t \mu(\varphi u_3^{(n)} u_4^{(n-1)})(s) ds. \end{aligned}$$

Integrate by parts with respect to s :

$$\begin{aligned} & - \int_0^t \mu(u_1^{(n)} \partial_s \varphi)(s) ds + \mu(u_1^{(n)} \partial_t \varphi)(t) - \mu(u_1^{(n)} \partial_t \varphi)(0) = - \\ & \int_0^t \mu(\varphi u_1^{(n)} u_2^{(n-2)})(s) ds + \lambda \int_0^t \mu(\varphi u_3^{(n)} u_4^{(n-1)})(s) ds - C_1 \int_0^t \mathcal{E}(\varphi, u_1^{(n)})(s) ds \end{aligned}$$

- Again the *relative entropy inequality* and the *logarithmic sobolev inequality* imply a weak solution in $[0, T]$.

- Estimate doesn't depend on $T > 0 \rightarrow$ global solution in $\mathbb{R}_+$.
- Solution are nonnegative since $u_i^{(n)} \geq 0$ are nonnegative.
- Uniqueness is proved in the same way.

The main chemical equation is the following

$$\sum_{i \in I} \alpha_i \mathcal{A}_i \rightleftharpoons \sum_{i \in I} \beta_i \mathcal{A}_i,$$

with $\alpha_i \neq \beta_i$ for any $i \in I$. The main PDE is

$$\partial_t u_i = C_i L u_i + (\beta_i - \alpha_i) \left(\prod_{j=1}^q u_j^{\alpha_j} - \prod_{j=1}^q u_j^{\beta_j} \right).$$

- Let $I_- = \{i \in I, \beta_i - \alpha_i > 0\}$ and $I_+ = \{i \in I, \beta_i - \alpha_i < 0\}$. We assume that $\forall i_- \in I_-, \exists j_+ \in I_+$ such that

$$\frac{C_{i_-}}{|\beta_{i_-} - \alpha_{i_-}|} = \frac{C_{i_+}}{|\beta_{i_+} - \alpha_{i_+}|},$$

Iterated procedure :

$$\begin{aligned} \partial_t u_{i_-}^{(n)} &= C_{i_-} L u_{i_-}^{(n)} \\ &+ (\beta_{i_-} - \alpha_{i_-}) \left(\frac{\prod_{j=1}^q (u_j^{(n-1)})^{\alpha_j}}{(u_{i_-}^{(n-1)})^{\alpha_{i_-} - 1}} u_{i_-}^{(n)} - \frac{\prod_{j=1}^q (u_j^{(n-1)})^{\beta_j}}{(u_{i_+}^{(n-1)})^{\beta_{i_+} - 1}} u_{i_+}^{(n)} \right). \end{aligned}$$

- For a weak solution, the logarithmic Sobolev constant has to be smaller when $\max\{\alpha_i, \beta_i\}$ and $|I|$ is big.
